

Python Practice Questions (Set 2)

Topics: Syntax, Output, Comments, Variables

Q11 (Easy) — Basic Print Write a program to print the sentence: `Learning Python is exciting!`

Q12 (Easy) — Print with Escape Characters Write a program that prints the following exactly, using escape characters:

```
She said, "Python is easy!"  
Line1  
Line2
```

Q13 (Easy) — Storing Different Data Types Create four variables storing an integer, a float, a string, and a boolean value. Print each variable along with its type using `type()`.

Q14 (Easy) — Single-line Comment Practice Write a program with three variables `subject1`, `subject2`, `subject3` storing marks. Add a single-line comment above each variable explaining what it stores, then print the total marks.

Q15 (Easy) — Print Without Newline Write a program to print `Hello` and `World` on the same line, with a space between them, using two separate `print()` statements (hint: use the `end` parameter).

Q16 (Easy) — Simple Variable Update Create a variable `count = 0`. Update it by adding `5` to it and print the new value.

Q17 (Easy) — Concatenating Strings Create two variables `first_name` and `last_name`. Concatenate them with a space in between and print the full name.

Q18 (Easy) — Comment Out Code The following code has a line that should not run. Comment it out so the program only prints `"Task complete"`.

```
python  
  
print("Starting task")  
print("Task complete")
```

(Comment out the first print statement.)

Q19 (Medium) — Print with Separator Write a program to print `2026-08-07` using the `print()` function's `sep` parameter, given the values `2026`, `08`, `07` stored in separate variables.

Q20 (Medium) — Dynamic Typing Create a variable `data`, first assign it an integer value, print its type, then reassign it a string value and print its type again. Explain in a comment why this works in Python.

Q21 (Medium) — Constants Convention Write a program that defines a "constant" `PI = 3.14159` (by naming convention) and uses it to calculate the circumference of a circle with radius `7`. Add a comment noting that Python doesn't enforce true constants.

Q22 (Medium) — Multiple Variables from a Single Value Using one line of code, assign the value `"Python"` to three variables `lang1`, `lang2`, `lang3`. Print all three to confirm they hold the same value.

Q23 (Medium) — Fixing Indentation Errors The following code has an indentation error. Identify and fix it:

```
python

age = 18
if age >= 18:
print("You can vote")
```

Q24 (Medium) — f-string Expressions Create variables `length = 8` and `width = 4`. Using an f-string, print: `The area of the rectangle is 32` where `32` is calculated directly inside the f-string (not stored in a separate variable).

Q25 (Medium) — Print Data Types Write a program that stores `10`, `10.5`, `"10"`, and `True` in four variables and prints whether each one is a number (int/float) or not, using `type()` checks in comments (no if-statements needed, just identify manually via comments).

Q26 (Medium) — Reserved Keyword Check Explain (via comments in code) why the following variable assignments are invalid, then rewrite them using valid names:

```
python

for = 10
True = "yes"
```

Q27 (Medium) — Print Special Characters Write a program to print a file path like `C:\Users\Name\Documents` correctly using an escape character.

Q28 (Medium) — Chained Assignment with Update Create variables `a = b = c = 5`. Then update only `b` to `10`. Print `a`, `b`, and `c` to show that changing `b` doesn't affect `a` and `c`.

Q29 (Medium) — Docstring as Comment Write a function `greet()` that prints `"Hello!"`, and add a docstring (triple-quoted string right after the function definition) explaining what the function does. Call the function once.

Q30 (Medium) — Debug the Program Find and fix all errors (syntax + logical) in the following code so it correctly prints `The sum of 5 and 3 is 8`:

```
python

num1 = 5
num2 = 3
sum = num1 + num2
print("The sum of" num1 "and" num2 "is" + sum)
```
