

Python Practice Questions (Set 3)

Topics: Syntax, Output, Comments, Variables

Q31 (Easy) — Print Numbers Write a program to print the numbers `1`, `2`, `3` separately using three `print()` statements.

Q32 (Easy) — Basic Arithmetic Output Create two variables `num1 = 15` and `num2 = 4`. Print the result of their addition, subtraction, multiplication, and division (four separate print statements).

Q33 (Easy) — Comment Above Code Write a program with a variable `temperature = 36.6`. Add a single-line comment above it stating that it stores body temperature in Celsius, then print it.

Q34 (Easy) — Boolean Variable Create a variable `is_raining` and set it to `False`. Print the variable along with a label, e.g. `Is it raining? False`.

Q35 (Easy) — Print Multiple Variables Create three variables `item = "Notebook"`, `price = 40`, `quantity = 3`. Print all three values in one `print()` statement, comma-separated.

Q36 (Easy) — Reassigning a Variable Create a variable `score = 50`. Print it, then reassign it to `75` and print it again.

Q37 (Easy) — Print with Tabs Write a program to print the following output using the tab escape character `\t`:

```
Name    Age
Ravi    22
```

Q38 (Easy) — End of Line Comment Write a program with two variables `length = 12` and `breadth = 5`, each having an **end-of-line comment** explaining what it represents. Print their sum.

Q39 (Easy) — Order of Print Statements Predict and then verify with code: what is the output order of the following?

```
python
```

```
print("A")
print("B")
print("C")
```

Write the code and confirm the output.

Q40 (Easy) — Negative Numbers Create a variable `balance = -250`. Print a message showing the balance value along with a label like `Account Balance: -250`.

Q41 (Medium) — Print Result of Expression Directly Without storing the result in a variable, print the output of `(7 + 3) * 2 - 4` directly inside `print()`.

Q42 (Medium) — Print with Multiple Separators Compared Create variables `a = 1`, `b = 2`, `c = 3`. Print them once with `sep=", "` and once with `sep=" | "`. Compare the two outputs.

Q43 (Medium) — Comment to Disable Multiple Lines Given the code below, comment out the second and third print statements only, so just the first and fourth lines execute:

```
python

print("Line 1")
print("Line 2")
print("Line 3")
print("Line 4")
```

Q44 (Medium) — Variable Type Change Tracking Create a variable `value = 5`. Print its value and type. Then reassign `value = 5.0` and print value and type again. Add a comment noting what changed.

Q45 (Medium) — Multiple Variables, Single Print, Custom End Create variables `x = 10`, `y = 20`. Print them separated by `sep=" - "` and ensure the `print()` statement ends with `!!!` instead of a newline (use `end`).

Q46 (Medium) — Identify the Output Without running it, determine what this code prints, then verify:

```
python
```

```
a = 5
b = a
a = 10
print(a, b)
```

Q47 (Medium) — Underscore in Numbers Write a program that stores the number `1000000` using underscores for readability (`1_000_000`) in a variable `population`, and print it.

Q48 (Medium) — Comment Explaining a Formula Write a program that calculates simple interest using `principal = 1000`, `rate = 5`, `time = 2`. Add a comment above the formula explaining the simple interest formula, then print the result.

Q49 (Medium) — Swapping Using Arithmetic (No Third Variable, No Tuple Unpacking) Create `m = 8` and `n = 12`. Swap their values using addition and subtraction only (no third variable, no `x, y = y, x`). Print before and after.

Q50 (Medium) — Spot the Variable Naming Issues Identify which lines below will cause an error and why, then rewrite the whole block so all variables are valid:

```
python

2total = 100
user-id = 5
_valid = True
final$ = 20
```
